NOTES

MECH 191 — Metallurgy · Week 7 Notes · fill in blanks & key terms as you go

01

What each test measures, how to read results, and which method fits which material

02

Charpy impact, the ductile-brittle transition, fatigue mechanisms, and the S-N curve

03

Traceability, acceptance criteria, common flags, and the technician's responsibility

SLIDE 2 *Class Agenda*

EXAMET-5-R-600-HD • 50-500×

Specimens to Check Out

- Specimen A — 1018 steel (Vickers indent)
- Specimen B — 1045 steel (Vickers indent)

How to check out the kit:

- 1 See instructor after class today
- 2 Sign out the specimen tray
- 3 Use the EXAMET-5 at your convenience
- 4 Return kit before leaving class
- 5 Submit completed module with your portfolio

Portfolio Handout — Module 6

- SLIDE 3** *Metallography Lab — Module 6 EXAMET-5-R-600-HD · 50–500×*

MECH 191 — Course & Unit Roadmap

Unit 1	Unit 2	Unit 3	Unit 4	Unit 5
Materials Fundamentals	Steel & Alloys	Testing & Quality	Manufacturing	Joining & Failure
Wk 1 Aug 24 Atomic Structure & Bonding	Wk 4 Sep 14 Carbon & Alloy Steels	Wk 7 ← here Oct 5 Mechanical Testing	Wk 10 Oct 26 Casting	Wk 14 Nov 23 Welding Processes
Wk 2 Aug 31 Mechanical Properties	Wk 5 Sep 21 Stainless & Cast Irons	Wk 8 Oct 12 NDT Methods	Wk 11 Nov 2 Forming	Wk 15 Nov 30 Weld Metallurgy & Failure
	Wk 6 Sep 28 Nonferrous & Phase Diagrams	Wk 9 Oct 19 Quality Standards	Wk 12 Nov 9 Machining	Wk 16 Dec 7 Corrosion & Wrap-up
			Wk 13 Nov 16 Powder Metallurgy	

Week 17 • FINAL EXAM

SLIDE 4 MECH 191 — Course & Unit Roadmap

NOTES

Topics

- Tensile testing — stress-strain curve, yield strength, UTS, elongation at fracture
- The 0.2% offset method for materials without a clear yield point
- Hardness testing — Rockwell (HRC, HRB), Brinell (HB), and Vickers (HV): methods and when each is used
- Charpy impact testing — notched specimens, energy absorption, and the ductile-brittle transition temperature
- Fatigue — cyclic loading, crack initiation at stress concentrations, the S-N curve, and the steel fatigue limit
- Reading a mill test report (MTR) — heat numbers, composition, mechanical test results, and traceability

Reference Material

Moniz Ch. 3
Mechanical Testing

Kalpakjian Ch. 2
Fundamentals of Mechanical Behavior

Stress-Strain Curve (Interactive)

Hardness Testing Scales
Impact & Fatigue Testing

NOTES

Try to answer these before we dive in — we'll revisit them with answers at the end of class.

- ## SLIDE 6 Core Questions

What the Test Measures

- Pulls a standardised specimen apart at a controlled rate while measuring force and extension
- Force and extension are converted to engineering stress ($\sigma = F/A_0$) and engineering strain ($\epsilon = \Delta L/L_0$)
- Results are plotted as a stress-strain curve — each point tells a different story about the material
- The 0.2% offset method is used when no clear yield point exists — draw a line parallel to the elastic slope from 0.2% strain; the intersection with the curve is the reported yield strength
- A single tensile test returns yield strength, UTS, elongation, and reduction in area — more data per test than any other routine test

Proportional limit:

Stress up to which σ - ϵ is linear — the elastic region

Yield strength (S_y):

Stress at onset of permanent plastic deformation — a primary design parameter

Ultimate tensile strength (UTS):

Maximum stress on the curve; necking begins at this point

Elongation at fracture:

Total permanent strain at fracture (%) — direct measure of ductility

Reduction in area:

% decrease in cross-section at fracture — especially useful for materials that neck heavily

Curve shape:

Long plastic plateau = tough and ductile; steep then abrupt fracture = brittle; no clear yield point = typical aluminum

NOTES

Hardness Testing — Three Methods, Three Applications

Method Comparison				
Method	Indenter	Load & Readout	Best For	Typical Scale
Rockwell	Diamond cone (HRC) Steel ball (HRB)	Minor + major load; depth readout instantly	Production inspection; finished parts	HRC 20–70 (hard steels) HRB 0–100 (soft metals)
Brinell	Hardened ball (10 mm, W/C)	High load; measure indent diameter optically	Castings, forgings, coarse-grained materials	HB / BHN up to ~650; approximate UTS from HB
Vickers	Square pyramid diamond (same for all)	Variable low loads; measure diagonals optically	Thin sections, coatings, precision & microhardness	HV 1–3000; converts across HRC/HB

Conversion Caution

Approximate conversion tables between HRC, HB, and HV exist — and approximate UTS can be estimated from HB ($UTS \approx 3.45 \times HB$ in MPa for carbon steels). These are approximations: use with caution on alloy steels and non-ferrous materials where the relationship differs.

Technician Rule of Thumb

Use Rockwell on the production floor for quick pass/fail checks. Use Brinell on rough or coarse-grained material where a small indentation would land in a soft spot. Use Vickers when measuring case depth, thin-wall sections, or individual microstructural phases.

SLIDE 8 Hardness Testing — Three Methods, Three Applications

NOTES

The Charpy Impact Test

- A notched rectangular specimen is supported at both ends; a swinging pendulum strikes from behind at the notch
- Energy absorbed = $mgh_1 - mgh_2$ (the difference between swing height before and after fracture), reported in Joules or ft-lbf
- The notch simulates a real stress concentration — a crack tip, undercut weld, sharp corner, or inclusion
- Tough materials absorb high energy and show large lateral expansion and shear fracture surfaces; brittle materials absorb little energy and show bright, flat, cleavage fracture surfaces
- Izod test: specimen clamped vertically and struck at the top — less common in modern standards than Charpy

Upper shelf:

High absorbed energy — fully ductile fracture. Material behaves toughly above the transition temperature.

Lower shelf:

Low absorbed energy — fully brittle fracture. Even a tough-looking material becomes dangerous below this temperature.

Transition temperature:

Defined at 50% of upper shelf energy (or 50% brittle fracture appearance). A material can pass room-temperature testing but be catastrophically brittle at service temperature.

BCC steels:

Carbon and low-alloy steels show a sharp DBTT — critical for arctic pipelines, offshore structures, and pressure vessels in cold service.

FCC metals:

Austenitic stainless, aluminum, copper remain tough at cryogenic temperatures — no DBTT. Essential for LNG and cryogenic applications.

SLIDE 9 *Impact Testing & the Ductile-Brittle Transition*

NOTES

How Fatigue Works

- ## The S-N Curve (Wöhler Curve)

Surface finish, notches, and residual stresses affect where the S-N curve sits — a polished surface in compression performs far better than a notched surface in tension.

NOTES

Reading a Mill Test Report (MTR)

The MTR is the chain of traceability between raw material and finished component — without it, there is no way to verify the material meets the specification.

01 Heat / Lot Number

Must match the number stamped or stencilled on the physical material. Without this match, the MTR does not certify the material in your hand.

02 Material Grade & Specification

Confirm it matches what was ordered — ASTM A36, API 5L Grade B, etc. A grade substitution not approved by engineering is a nonconformance.

03 Chemical Composition

Compare each element against the specification limits — carbon, manganese, phosphorus, and sulfur always; alloying elements as required by the grade.

04 Mechanical Test Results

Yield strength, UTS, and elongation at minimum; impact values if required. Compare each against the minimum (or maximum) acceptance criteria.

05 Test Standard & Certifying Signature

Tests must be performed to the correct standard (e.g. ASTM A370). The document must be signed and traceable to an accredited testing facility.

SLIDE 11 *Reading a Mill Test Report (MTR)*

NOTES

Technician's Perspective — When Results Have Real Consequences

Red Flag: MTR heat number mismatch

The heat number on the MTR does not match the number stencilled on the pipe. Stop — do not use the material. Tag it as quarantined, issue a nonconformance report, and notify the quality engineer. A material whose identity cannot be confirmed cannot be installed in a code-governed system.

Caution: Impact values just at minimum

The Charpy values in the MTR meet the specification — but they are at the minimum allowable limit on a project with a low minimum service temperature. Flag it to the engineer before installation. Minimum-conforming is not always fit-for-purpose when temperatures drop below the tested range.

Good Practice: Hardness survey after welding

After welding P91 chrome-moly pipe, a Vickers microhardness survey is run across the weld, HAZ, and base metal. Hard spots above the limit indicate insufficient post-weld heat treatment — the weld must be heat-treated again before pressure testing. The test caught a problem before the system went into service.

SLIDE 12 *Technician's Perspective — When Results Have Real Consequences*

NOTES

What does a tensile test measure and what do the results tell you?

Rockwell vs. Brinell hardness — what's the difference and when is each used?

Why is impact testing important and what is the ductile-brittle transition?

What is fatigue and why can a metal fail below yield strength?

How do you read a mill test report?
